## **INTRODUCTION & PURPOSE**

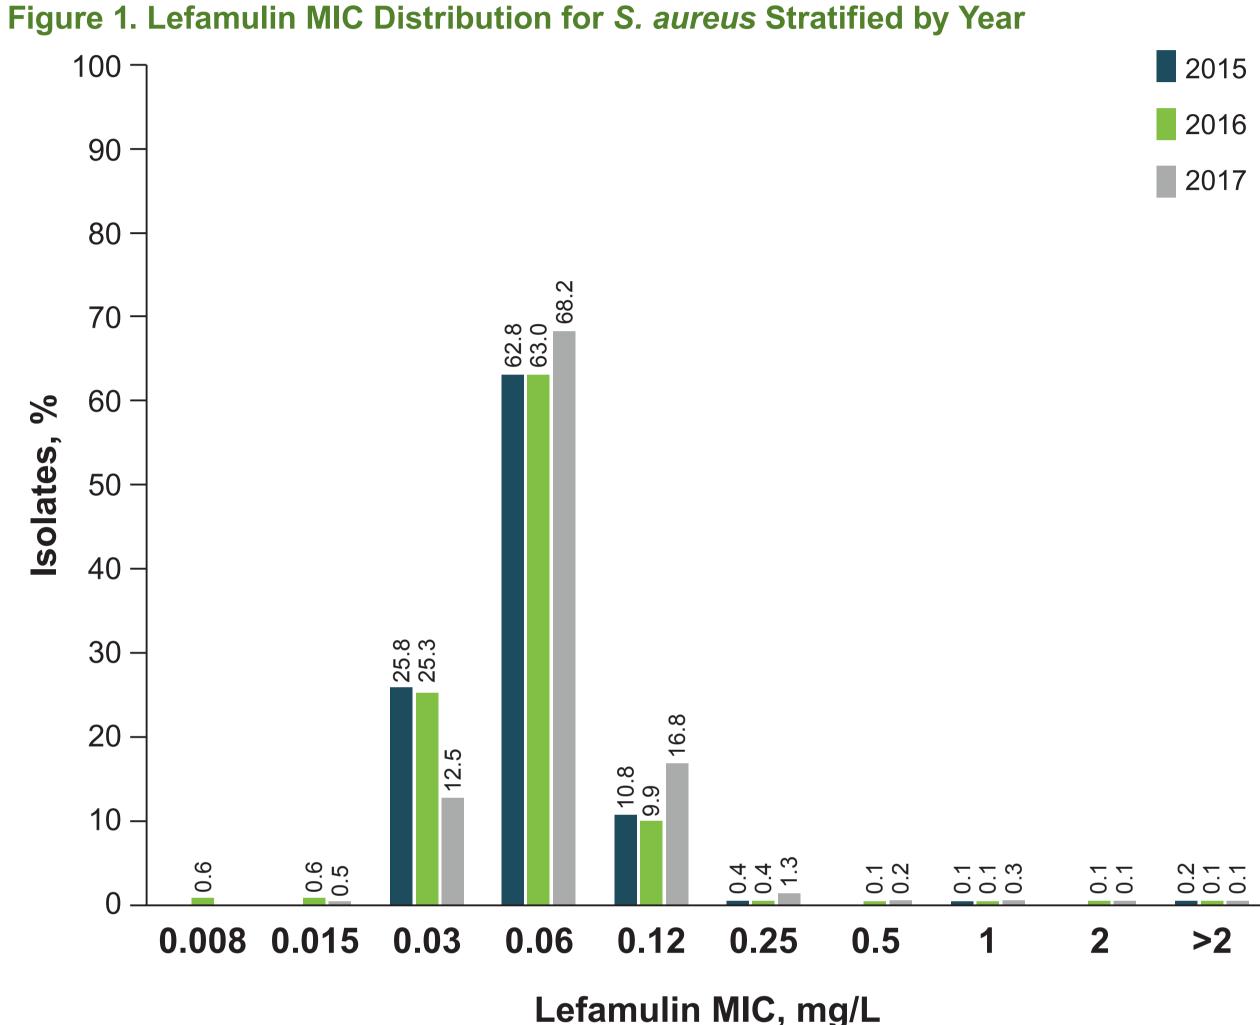

- Lefamulin (LEF) is a semisynthetic pleuromutilin antibiotic in late-stage clinical development for intravenous (IV) and oral treatment of community-acquired pneumonia (CAP) and acute bacterial skin and skin structure infections (ABSSSI)
- LEF inhibits protein synthesis by binding the 50S ribosomal subunit at the A- and P-sites in the peptidyl transferase centre
- LEF has demonstrated activity against a variety of pathogens, including those commonly associated with CAP and ABSSSI, and its activity is not influenced by resistance to other antimicrobial classes
- In a recent phase 3 trial for the treatment of CAP (ClinicalTrials.gov identification number NCT02559310), LEF (150 mg IV q12h or for 5–7 days) was noninferior to moxifloxacin ± linezolid (400 mg IV q24h for 7 days) when patients initiated IV drug with optional oral switch (600 mg LEF q12h or 400 mg moxifoxacin q24h).<sup>1</sup> LEF noninferiority to moxifloxacin was also observed in a second phase 3 trial when patients received oral LEF 600 mg q12h for 5 days or oral moxifloxacin 400 mg q24h for 7 days (ClinicalTrials.gov identification number NCT02813694)<sup>2</sup>
- The objective of this investigation was to evaluate the *in vitro* activities of LEF and comparators against clinical bacteria collected worldwide during 3 years of surveillance

## METHODS

- 15,036 bacterial isolates, including 6018 Streptococcus pneumoniae and 4463 Staphylococcus aureus isolates, among others, were collected from medical centres in Europe (n=5712 [19 nations]), the United States (n=5731), the Asia-Pacific region (APAC; n=2132 [10 nations]), and Latin America (n=1461 [6 nations]) from 2015–2017 as part of the SENTRY Antimicrobial Surveillance Programme
- Susceptibility was tested against LEF and numerous comparators by reference broth microdilution method according to Clinical and Laboratory Standards Institute guidelines<sup>3</sup> at a central laboratory
- The following proposed LEF breakpoints were applied:  $\leq 0.5$  mg/L for Staphylococcus spp., viridans group streptococci, and *Moraxella catarrhalis*; ≤1 mg/L for *S. pneumoniae*; ≤0.25 mg/L for  $\beta$ -haemolytic streptococci;  $\leq 4$  mg/L for *Haemophilus influenzae*; and  $\leq 8$  mg/L for Haemophilus parainfluenzae
- LEF resistance mechanisms were evaluated by whole genome sequencing and in silico analysis

## RESULTS

- LEF was active against S. aureus independent of oxacillin resistance (minimum concentration at which 50% or 90% of the isolates were inhibited [MIC<sub>50/90</sub>], 0.06/0.12 mg/L); only 9 (0.2%) isolates exhibited LEF minimum inhibitory concentration (MIC) >1 mg/L, and oxacillin resistance varied from 22.3% (Europe) to 41.4% (United States; 32.1% overall; **Tables 1** and **2**)
- LEF activity against S. aureus remained very stable over the study period (Figure 1)
- LEF was highly active against S. pneumoniae (MIC<sub>50/90</sub>, 0.06/0.12 mg/L; highest MIC, 1 mg/L; Table 1) and retained activity against isolates resistant to penicillin (MIC, >2 mg/L [EUCAST], n=311), erythromycin (n=2080), tetracycline (n=1424), and/or trimethoprim-sulfamethoxazole (n=1091), with MIC<sub>50/90</sub> of 0.06/0.12 mg/L for these subsets (Figure 2)
- LEF was also active against levofloxacin-resistant (MIC, >2 mg/L [EUCAST]) isolates (n=86; MIC<sub>50/90</sub>, 0.06/0.25 mg/L; **Figure 2**)
- Overall rates of S. pneumoniae susceptibility to penicillin (at ≤0.06 mg/L), amoxicillin-clavulanate, azithromycin, and tetracycline were 65.0%, 93.5%, 65.6%, and 75.9%, respectively, and susceptibility rates were generally lower in APAC compared with other regions (Table 1)
- LEF exhibited similar activity against  $\beta$ -lactamase–positive (24.2% overall) and –negative *H. influenzae*, with MIC<sub>50/90</sub> of 0.5/1 mg/L for both groups (**Tables 1** and **2** show all *H. influenzae*) isolates combined)
- LEF MIC values were generally low among  $\beta$ -haemolytic streptococci (MIC<sub>50/90</sub>, 0.03/0.03 mg/L), with only 5 (0.6%, all Streptococcus agalactiae) isolates showing MIC >0.12 mg/L (Tables 1 and 2)
- LEF was also active against coagulase-negative staphylococci (MIC<sub>50/90</sub>, 0.03/0.12 mg/L), viridans group streptococci (MIC<sub>50/90</sub>, 0.06/2 mg/L), and *H. parainfluenzae* (MIC<sub>50/90</sub>, 1/4 mg/L; **Table 1**)
- Isolates with elevated LEF MIC results (compared with the wild-type population) were rare and mainly caused by vga(A) in staphylococci and Isa(E) in streptococci (data not shown); the methyltransferase *cfr* was detected in only 2 coagulase-negative staphylococci (in 2016), whereas not a single *cfr*-positive isolate was detected in *S. aureus* in the complete 2015–2017 testing period

MIC=minimum inhibitory concentration

### 29<sup>th</sup> European Congress of Clinical Microbiology and Infectious Diseases; April 13–16, 2019; Amsterdam, Netherlands

## CONCLUSIONS

Latin America:

d viridans group streptococci, luenzae are shown in brackets

### LEF displayed stable and potent *in vitro* activity against a large, 3-year, contemporary worldwide collection of bacterial isolates regardless of resistance phenotype to other antibiotic classes, including $\beta$ -lactams, tetracyclines, macrolides and fluoroquinolones, among others

- Percentages of isolates with elevated LEF MIC values (putative resistant) were very low and primarily caused by target protection by ATP-binding cassette F (ABC-F) proteins such as vga(A, E), lsa(E), and sal(A), respectively, whereas cfr has hardly been detected (2 of >15,000 total tested isolates)
- The coverage of CAP pathogens including resistant isolates (this study) and atypical respiratory pathogens (demonstrated in other studies) supports the ongoing clinical development of LEF as an empiric IV and oral monotherapy for the treatment of CAP and other respiratory tract infections
